Macrocyclic and supramolecular coordination chemistry

Leroy Cronin

Department of Chemistry, The University of Glasgow, University Avenue, Glasgow, UK G12 8QQ

There are an ever increasing number of interesting and complex supramolecular architectures being designed and isolated. However, a slight shift is detected towards an increasing focus on the application of the supramolecular concept to the area of functional materials, sensors and components for molecular electronics and nanofabrication. An ultra-large \{Mn_{84}\} wheel-shaped cluster has been isolated\(^{26}\) that is a single-molecule magnet (SMM). Many new types of cluster frameworks have been synthesized, some notably \(e.g.\) \(\text{Fe}_{14}\) using hydrothermal methods.\(^{35}\) Polyoxometalate clusters provide paradigms for cation capture and filtering,\(^{90-92}\) whereas ligand design has allowed access to a vast range of molecular grids,\(^{141}\) cubes,\(^{131,132}\) boxes\(^{129}\) and other complexes with interesting functionality \(e.g.\) solvatochromism,\(^{178}\) Zn(II)-sensors\(^{163}\) and a nanovalve.\(^{139}\)

1 Introduction and scope

This report focuses on the development in design, synthesis and self-assembly of metal-based architectures and on the ligands designed to aid the construction of metallo-supramolecular architectures. Although particular attention will be paid to discrete molecular architectures, infinite networks and polymers will be included where new and interesting ligands or metal-based moieties are discovered that are of consequence to the general area. Furthermore, a section on supramolecular and macrocyclic devices has been included to reflect a broader transition in the field to increasingly exploit and create functional devices and materials.

In the past decade supramolecular chemistry has been transformed by the revolution in small molecule crystallography and much of the interest in this area lies in the manipulation, understanding and construction of new architectures and topologies. Therefore many crystal structures have been included in this report to aid visualisation and conceptualisation of the many interesting metallo-supramolecular architectures that have been constructed.\(^{1}\) A common colour scheme/size scheme is used in all the structural figures unless otherwise stated; the carbon atoms are light grey, nitrogen atoms white, metal ions large black spheres, sulfur atoms large grey spheres, oxygen atoms small black spheres.
2 Macrocyclic ligands

The ion-induced assembly of tubular conjugated Schiff-base macrocycles into supramolecular assemblies has been accomplished using a new, well-defined conjugated macrocycle. These macrocycles (L¹ and L²) contain three tetradequate \{N₂O₂\} binding sites organized in an equilateral triangle, as well as a pocket in the centre that is surrounded by six phenolic oxygen atoms resembling [18]crown-6. Complexation with a range of small cations (M⁺ = Li⁺, Na⁺, K⁺, Rb⁺, Cs⁺, NH₄⁺) causes a change in the physical properties that can be attributed to the formation of ionic assemblies.

The efficiency of a series of amino-azacryptands (L³–L₁₆) for encapsulation and extraction of the oxoanions pertechnetate and perrhenate (Fig. 1) from aqueous solution were investigated and compared with that of their open-chain counterparts. The aqueous formation constants for oxoanion association with the cryptands were determined by pH potentiometry and NMR and X-ray studies providing evidence for encapsulation. Interestingly, the extractabilities could not be explained solely on the basis of ligand lipophilicity; the level of protonation also plays an important role.

Anion effects in selective bifunctional metal salt extractants based on aza-thioether macrocycles has been examined whereby coordination of a metal cation to L¹₇ breaks internal hydrogen bonding to allow anions to bind to the inner urea hydrogen site on the attached pendant arm. No anion binding occurs in the absence of a bound metal ion. Two-phase metal extraction studies with AgX salts and L¹₇ confirm that the anion plays an important role, although it is likely that solubility of the resulting metal complexes in the organic phase is the predominant factor. The related macrocycle, L¹₈, where a sulfur donor replaces the ether oxygen in L¹₇, produces very similar results to those found for L¹₈ with all of the Ag salts used. This indicates that
L₁₈ also functions as a heteroditopic ion-pair receptor for AgNO₃ and AgClO₄. Indeed, chelate ring sequence effects on thermodynamic, kinetic and electron-transfer properties of heteroleptic ligands has recently been discussed.⁵

Primary and secondary coordination to scandium(III) has been examined with the crown ethers 15-crown-5 (L₁⁹), 18-crown-6 (L₂⁰) and 12-crown-4 (L₂¹) whereby hydrated scandium nitrate and the crown ethers react in ethanol solution to form a surprisingly diverse range of structural types containing the crown ethers hydrogen-bonded to the scandium-aquo-nitrato or scandium-aquo-hydroxo-nitrato complexes.⁶

The development of bio-inspired chelates with hydrogen-bond donors has been accomplished with the synthesis of the new multidentate tripodal compounds

Fig. 1  Structure of L⁵ complexed to ReO₄²⁻ via hydrogen-bonded interactions (dashed lines).

L¹⁸ also functions as a heteroditopic ion-pair receptor for AgNO₃ and AgClO₄. Indeed, chelate ring sequence effects on thermodynamic, kinetic and electron-transfer properties of heteroleptic ligands has recently been discussed.⁵

Primary and secondary coordination to scandium(III) has been examined with the crown ethers 15-crown-5 (L¹⁹), 18-crown-6 (L²⁰) and 12-crown-4 (L²¹) whereby hydrated scandium nitrate and the crown ethers react in ethanol solution to form a surprisingly diverse range of structural types containing the crown ethers hydrogen-bonded to the scandium-aquo-nitrato or scandium-aquo-hydroxo-nitrato complexes.⁶

The development of bio-inspired chelates with hydrogen-bond donors has been accomplished with the synthesis of the new multidentate tripodal compounds

bis\((N'\text{-}\text{tert-}
\text{butylureido})\text{-}N\text{-ethyl}\)\text{-}2\text{-}pyridylmethylamine \((H_4L^{22})\) and bis\((N'\text{-}\text{tert-}
\text{butylureido})\text{-}N\text{-ethyl}\)\text{-}N\text{-}methylamine \((H_4L^{23})\).\(^7\)

These ligands contain two ureaethylene arms that, when deprotonated, bind to a metal ion and position two hydrogen-bond donors near the metal centre so that formation of intramolecular H-bonds with coordinated species is possible. The structure of the monomeric metal acetate complexes of \(H_4L^{22}\) and \(H_4L^{23}\) contain an intramolecular hydrogen bond (Fig. 2).

---

**Fig. 2** Structure of \(L^{22}\) complexed to Fe(OAc) (LHS) with one intramolecular H-bond, and structure of \(L^{23}\) complexed to Fe(OAc) (RHS) with two intramolecular H-bonds.
Pyridine-containing macrocycles bearing aminopropyl pendant arms (L\textsuperscript{24}, L\textsuperscript{25}) have been synthesized by template condensation.\textsuperscript{8,9} This template condensation was carried out with nickel(II) and copper(II) salts. Demetallation of the nickel(II) macrocycles yielded stable pentadentate ligands that were used for the preparation of the copper(II) complexes. Also the cyclen derivatised with hydroxyethyl pendant arms (L\textsuperscript{26}) forms a diverse range of mononuclear and polynuclear lanthanide(III) complexes.\textsuperscript{10}

The complexation of dipyridine-containing macrocyclic polyamines L\textsuperscript{27} and L\textsuperscript{28} with different binding units has been examined.\textsuperscript{11}

Coordination of these macrocycles to copper(II) and nickel(II) salts has been investigated with potentiometric and spectrophotometric UV-vis titrations in aqueous solutions (Fig. 3). While in L\textsuperscript{27} all the nitrogen donor atoms are convergent inside the macrocyclic cavity, in L\textsuperscript{28} the heteroaromatic nitrogen atoms are located outside.

The stability and structure of mono- and di-nuclear Cu(II), Ni(II) and Zn(II)
complexes of pyrazole- and triazole-bridged bis-macrocycles has been examined. The two ligands $L^{29}$ and $L^{30}$ complex with copper(II), nickel(II) and zinc(II) salts to form a series of mononuclear $[ML^{29-30}H_n]^{(n+2)+}$ ($n = -3, -2, -1, 0, 1, 2$) and dinuclear species $[M_2L^{29-30}H_m]^{(m+4)+}$ ($m = 0, -1, -2, -3$).

A new Schiff-base macrocycle is obtained by the lead(II) ion-templated $[2 + 2]$ condensation of 3,5-diacetyl-1$H$-1,2,4-triazole and 1,4-diaminobutane in the presence of sodium hydroxide. Transmetallation of the resulting di-lead complex, $\text{Pb}_2(L^{31})(\text{ClO}_4)_2$, in acetonitrile with two equivalents of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ leads to the isolation of an orange, six-coordinate complex, $[\text{Co}^+\text{II}(L^{31})(\text{NCO})_2]$, which is the first structurally characterized complex of a triazolate-containing macrocycle to date (Fig. 4).

The interaction of a series of successively $N$-benzylated derivatives of cyclam, $L^{32-36}$, with selected transition and post-transition metal ions has been investigated.
A novel imidazolate-bridged heterodinuclear Cu(II)–Zn(II) complex has been derived from a macrocyclic ligand, L\textsuperscript{37}, with two hydroxyethyl pendants.\textsuperscript{15} Hexadentate tris-salicylaldimine ligands (L\textsuperscript{38–42}) bearing ortho-N-dialkylaminomethyl substituents have been shown to function as ditopic ligands for NiSO\textsubscript{4} or NiCl\textsubscript{2}.\textsuperscript{16} The incorporation of the Ni ion into the [N\textsubscript{3}O\textsubscript{3}]\textsuperscript{3−} site templates

\begin{equation}
\text{Fig. 4} \quad \text{Representation of the structure of } [\text{Co}^{\text{II}}(L^{31})(\text{NCO})_2].
\end{equation}
the pendant alkylammonium groups to allow them to hydrogen bond to the attendant anion(s). Formulation as complexes of the trianionic/tricationic ligand is supported by X-ray structure determinations of solvated forms of the complexes [Ni(L^41)SO_4] and [Ni(L^41)Cl]Cl. The kerosene-soluble ligand L^40 functions as a good extractant for nickel salts, showing high selectivity for recovery of NiCl_2 over NiSO_4 and demonstrates the potential of these novel zwitterionic extractants for nickel(II) salts.

The syntheses of several novel copper(I) and copper(II) compounds containing triazacyclohexanes with one or three 2-pyridylmethyl substituents (L^43, L^44) are described. In particular, the complex of L^44 reacts with dioxygen to form a complex with a Cu_4(OH)_4 cubane core.

The potentially nonadentate ligand H_3L^45 has been synthesized and complexed with several lanthanide ions. The resulting complexes have high water solubility and show highly rigid C_3-symmetric solution structures. Furthermore, all the complexes present mononuclear nine-coordinated solid-state structures and the coordination polyhedron is a slightly distorted, tri-capped trigonal prism.

A unique trinickel(II) complex has been synthesized using the novel triple-salen ligand H_6L^46, which bridges three Ni(II)-salen units through a meta-phenylene linkage.
The complexation of palladium(II) by a unique family of [2 + 2] diiminodipyrromethane macrocycles (L\textsuperscript{47}, L\textsuperscript{48}) yields compounds that adopt structures reminiscent of Pac-Man porphyrins (Fig. 5).\textsuperscript{20}

A novel family of redox-active, dinuclear transition metal-based cryptands self-assembled from dithiocarbamate ligands (L\textsuperscript{49}) has been synthesized.\textsuperscript{21} Further, depending upon the nature of the spacer groups, these new cryptand systems have been shown, \textit{via} electrochemical studies, to recognise the binding of cations or anions.

\textbf{Fig. 5} Representation of the structure of [Pd\textsubscript{2}(L\textsuperscript{47})].

\begin{center}
\includegraphics[width=0.8\textwidth]{structure.png}
\end{center}

H\textsubscript{3}L\textsuperscript{67} R = H  \\
H\textsubscript{3}L\textsuperscript{68} R = Ph

The aggregation of metallo-supramolecular meso and helical dimeric architectures has been observed when the periphery of the ligands $L^{50}$ or $L^{51}$ are derivatised with a hydroxy ligand. The hydrogen-bond sites aggregate the architectures into polymeric arrays, with the selection of anion determining whether this is self-H-bond aggregation or anion-mediated H-bond aggregation.

A new ditopic ligand based upon a 2,7-disubstituted naphthalene bearing two terpy-terminated bis(ethyleneoxy) substituents, $L^{52}$, has been prepared and shown to give a conformationally locked [1 + 1] macrocycle upon reaction with iron(II) salts (Fig. 6).

The new ligands $R,R$-trans-$S,S'$-bis[methyl(2'-quinolyl)]-1,2-dithiacyclohexane ($L^{53}$), $cis-S,S'$-bis[methyl(2'-quinolyl)]-1,2-dithiacyclohexane ($L^{54}$), and 1,6-bis(2'-quinolyl)-2,5-dithiahexane ($L^{55}$) have been synthesized and their complexes with copper(I) and copper(II) prepared. The ligand/metal systems are bistable, as the complexes with copper in both its oxidation states are stable under the same conditions as solids and in solution.

A series of structurally characterized copper complexes of two pyridazine-spaced cryptands in redox states + (I,1), (II,1), (II), (II,II) are reported. The hexa-imine cryptand $L^{56}$ [formed by the 2 + 3 condensation of 3,6-diformylpyridazine with tris(2-aminoethyl)amine (tren)] is able to accommodate two non-stereochemically
demanding copper(I) ions, resulting in \([\text{Cu}^+L^{56}](\text{BF}_4)_2\), or one stereochemically demanding copper(II) ion, resulting in \([\text{Cu}^{II}L^{56}](\text{BF}_4)_2\). The structurally characterized, octa-amine cryptand \(L^{57}\), prepared by sodium borohydride reduction of \(L^{56}\), is therefore more flexible (Fig. 7).²⁵

3 Metallomacrocycles and cyclic clusters

The largest single-molecule magnet (SMM), a \(\{\text{Mn}_{84}\}\) cluster wheel of composition \([\text{Mn}_{84}\text{O}_{72}(\text{O}_2\text{CMe})_{78}(\text{OMe})_{24}(\text{MeOH})_{12}(\text{H}_2\text{O})_{42}(\text{OH})_6]\), has recently been discovered
This represents the largest wheel cluster comprising first row transition metal ions and has an inner diameter of 1.9 nm and an outer diameter of 4.2 nm, and is 1.2 nm thick. This was synthesized using $[\text{Mn}_{12} \text{O}_{12}(\text{O}_2\text{CMe})_{16}(\text{H}_2\text{O})_4]$ as a precursor. The wheels line up in the solid state to reveal a nanoporous supramolecular nanotube, and magnetic studies of this cluster reveal SMM-type behaviour at 1.5 K.

The formation of several new wheel-type clusters derived from the parent $[\text{Cr}_8 \text{F}_8(\text{O}_2\text{CCMe}_3)_{16}]$ has been accomplished. If this $\{\text{Cr}_8\}$ wheel is synthesized in the presence of a secondary amine then a new type of open ring, or horseshoe, of the formula $[\text{Cr}_6 \text{F}_{11}(\text{O}_2\text{CCMe}_3)_{10}]^{3-}$ ($\text{O}_2\text{CCMe}_3 = L^{58}$) is generated (Fig. 9). However, if a second metal ion that does not favour an octahedral geometry is added, further new structural types are formed, e.g. $[\text{Cr}_6(\text{VO})_2 \text{F}_8(\text{O}_2\text{CCMe}_3)_{15}]$, when the reaction is

Fig. 6  Representation of the structure of $[\text{Fe}(L^{52})]^{2+}$.
carried out in the presence of vanadyl acetate. A new distorted structural type is formed in the presence of basic copper carbonate in the form of \([\text{Cr}_{10}\text{Cu}_2\text{F}_{14}(\text{O}_2\text{CCMe}_3)_{22}]^{2+}\). The inclusion of zinc(II) causes the formation of a regular wheel \([\text{Cr}_7\text{ZnF}_8(\text{O}_2\text{CCMe}_3)_{16}]^{2+}\) whereby the zinc(II) can be located within the ring (Fig. 9).

![Fig. 7](image1.png)  
Fig. 7  Representation of the structure of \([\text{Cu}_2\text{L}^{56}]\) (LHS) and \([\text{Cu}_2\text{L}^{57}]\) (RHS).

![Fig. 8](image2.png)  
Fig. 8  Representations of the structure of \(\{\text{Mn}_{84}\} = [\text{Mn}_{84}\text{O}_{72}(\text{O}_2\text{CMe})_{78}(\text{OMe})_{24}(\text{MeOH})_{12}^{-}(\text{H}_2\text{O})_{42}(\text{OH})_{4}]\) wheel cluster (top view LHS, side view RHS).
A novel anion encapsulation process has been found to give rise to neutral supramolecular assemblies of cyclic copper(II)-based complexes. In this work a series of five polymerization isomers, \([\{\text{cis-Cu}^{II}(\mu\text{-OH})(\text{L}^{59})\}^n\] \((n = 6, 8, 9, 12, \text{ and } 14; \text{L}^{59} = \text{pz})\), is formed (Fig. 10). The metallacyclic ring sizes are not dependent upon the nature of the encapsulated anion: 6-membered rings are part of the structures...
where \( n = \{6 \text{ and } 12\} \) and when \( n = 6, 12 \) and 9, whereas 9-membered rings are encountered when \( n = \{6, 12\} \) and 9 and \( n = \{18, 14, \text{ and } 9\} \). The aggregation of metallacycles is specific to the encapsulated anion: the smaller chloride finds a snug fit between two 6-membered rings, and the planar carbonate requires a 6- and a 9-membered ring, whereas the tetrahedral sulfate is encapsulated among 8-, 9- and 14-membered rings. The structures of the series of metallacycles \([\{\text{cis-} \text{Cu(}\mu-\text{OH})(\mu-L^{59})\}_{n}]\) (\( n = 6, 8, 9, 12, \text{ and } 14 \)) resemble those of crown ethers and natural ionophores and can be considered as fully protonated, copper-containing metallacrowns.

The generation of ‘XMY’ species as potential monomers for forming \([\text{M(}\mu-X)(\mu-Y)]_n\), an oligomer or polymer based on the edge-connectivity of a tetrahedron, was recently shown to produce a diverse range of complexes. In this way, it could be expected that the controlled aggregation of low-coordinate, transition metal complexes can lead to the generation of unusual oligomers, polymers or clusters based on \([\text{Fe(}\mu-\text{Cl})(\mu-\text{SSiBu}_3)]_{12}\). For instance, \([\text{Fe(}\mu-\text{I})(\mu-\text{SSiBu}_3)]_{14}\) was formed (Fig. 11) using this idea along with the related \([\text{Fe(}\mu-\text{I})(\mu-\text{SSiBu}_3)]_{14}\).

A \( \text{Dy}_{10}(\text{OC}_2\text{H}_4\text{OCH}_3)_{30} \) (\( \text{OC}_2\text{H}_4\text{OCH}_3 = \text{L}^{60} \)) has been self-assembled that represents the largest lanthanide ring to be obtained without some kind of template. This demonstrates that large rings also occur for the lanthanides even with simple oxygen donor ligands without template effects (Fig. 12).

A metallamacrocycle containing 12 \( \text{Zn}^{2+} \) ions, making it the largest member of a family of pyrazole-bridged cyclic metal clusters, has been synthesized from the reaction of \([\text{Zn(ClO}_4)_2]\) with 5-methyl-3-phenylpyrazole, 2-mercaptoethanol, and...
NaOH to give the hexameric, dodecanuclear metallamacrocycle \([\text{Zn}_2(L^{61})_2-(\text{OCH}_2\text{CH}_2\text{S})_6]\) (\(L^{61} = 5\)-methyl-3-phenylpyrazole). The cluster is formally neutral as the +24 charge of the 12 \(\text{Zn}^{2+}\) centres is balanced by the 12 deprotonated pyrazole rings and the six doubly-deprotonated 2-mercaptoethanol molecules.  

Alcoholysis of \([\text{Fe}_6\text{O}_2(\text{OH})_2(\text{O}_2\text{CtBu})_{10}(L^{62})_2]\) affords ferric wheels of different nuclearities (\(L^{62} = \) the anion of 2-(hydroxyethyl)pyridine). Hydrolysis in methanol yields \([\text{Fe}_{10}(\text{OMe})_{20}(\text{O}_2\text{CtBu})_{10}]\), whereas phenol gives the structurally unprecedented wheel \([\text{Fe}_8(\text{OH})_4(\text{OPh})_8(\text{O}_2\text{CtBu})_{12}]\), and is the first to contain phenoxide.  

Whereas alcoholysis of preformed tetranuclear and hexanuclear iron(III) clusters has been employed for the synthesis of four higher-nuclearity clusters, treatment of \([\text{Fe}_4\text{O}_2(\text{O}_2\text{CMe})_7(\text{bpy})_2](\text{ClO}_4)\) with phenol affords the hexanuclear cluster \([\text{Fe}_6\text{O}_3(\text{O}_2\text{CMe})_9(\text{OPh})_2(\text{bpy})_2](\text{ClO}_4)\). Reaction of \([\text{Fe}_6\text{O}_2(\text{OH})_2(\text{O}_2\text{CR})_{10}(\text{hep})_2]\) \((R = ^1\text{Bu or Ph}; \text{hep} = \) deprotonated 2-(2-hydroxyethyl)pyridine) with \(\text{PhOH}\) affords the new ‘ferric wheel’ complexes \([\text{Fe}_8(\text{OH})_4(\text{OPh})_8(\text{O}_2\text{CR})_{12}]\) \((R = ^1\text{Bu or Ph})\).

The reaction of the sodium salt dihydrate of 2-mercaptocinnamic acid (\(\text{H}_2L^{63}\)) with di-n-butyltin dichloride in benzene affords a novel 18-tin-nuclear macrocyclic complex, which is a highly centrosymmetric 48-member macrocycle containing two centrosymmetric ladders of hydrolysis (Fig. 13).

### 4 Cluster frameworks

A tetradecametallic \(\text{Fe}^{II}\) cluster has been synthesized under hydrothermal conditions by heating a solution of \([\text{Fe}_3\text{O}(\text{O}_2\text{CMe})_6(\text{H}_2\text{O})_3]\) in methanol in the presence of the potential bridging ligand benzotriazole (\(\text{BtaH}; \text{HL}^{64}\)) at 100 °C for 12 h. The cluster
has the composition, \([\text{Fe}_{14}(L^{64})_6\text{O}_6(\text{OMe})_{18}\text{Cl}_6]\) (Fig. 14). The complex has pseudo-three-fold symmetry and the metallic core can be described as a hexa-capped hexagonal bipyramid with the caps on alternate faces. Preliminary magnetic investigations suggest that this cluster has a magnetic ground state where \(S = 23\) representing the highest spin state so far found for a pure-iron cluster.35

Phosphonate-based ligands have recently been utilised in the formation of polymetallic iron complexes by the reaction of the well-known Fe(III) carboxylate...
triangles $[\text{Fe}_3\text{O}((\text{O}_2\text{CR})_3\text{H}_{2}\text{O})_3\text{X}, (\text{R} = \text{H, CH}_3, \text{Ph or CMe}_3; \text{X} = \text{NO}_3^- \text{or Cl}^-)$] with phenylphosphonate. The variation of $\text{R}$ and $\text{X}$ gives rise to a number of cages, e.g., $[\text{Fe}_6\text{O}((\text{OH})_3(\text{O}_2\text{CMe})_3(\text{O}_2\text{PPPh})_4(\text{py})_9](\text{NO}_3)_2$, Fig. 15, $(\text{R} = \text{CMe}_3, \text{X} = \text{NO}_3^-)$, and $[\text{Fe}_4\text{O}((\text{C} \phi\text{Ph})_3(\text{O}_2\text{PPPh})_3(\text{py})_3] (\text{R} = \text{Ph}, \text{X} = \text{Cl}^-)$. Further variation in the amount of pyridine changes the reaction path yielding several more complexes.\(^{36}\) The use of phosphonate ligands has been extended to cobalt(II) and alkali metal ions whereby the ligands ‘encourage’ a Platonic relationship between cobalt(II) and alkali metal ions. The metal core has a high symmetry related to a Platonic solid and the choice of alkali metal used in the base used for deprotonation appears to influence the resulting structures.\(^{37}\)

The dipyrrolide ligand $\text{H}_2\text{L}\text{65}$ promotes the formation of a unique tetranuclear iron(II) compound that contains both diazaferrocenyl and distorted-tetrahedral iron centres.\(^{38}\)

Two distinct types of iron coordination are observed: one is distorted tetrahedral in which the iron is $\sigma$-bound to four pyrrolide nitrogens; the other octahedral with $\eta^5$-bonding to two pyrrolide rings so forming a diazaferrocene unit (Fig. 16).
The reaction of anhydrous FeCl₃ with HL₆₅ in MeOH produces the pentanuclear complex [Fe₅O₂(OMe)₂(L₆₄)₄(HL₆₄)(MeOH)₅Cl₅], containing a distorted tetrahedron of four Fe ions centred on a fifth Fe. The central Fe is antiferromagnetically-coupled to the peripheral Fe ions resulting in an $S = 15/2$ spin ground state. The reaction of [NEt₄]₂[Fe₂OCl₆] with sodium benzoate, 4,6- dimethyl-2-hydroxypyrimidine (L₆₆), and 1,1,1-tris(hydroxymethyl)ethane (H₃L₆₇) gives the undecametallic compound [NEt₄][Fe₁₁O₄(O₂CPh)₁₀(L₆₇)₄(L₆₆)₂Cl₄]. Magnetic measurements indicate an $S = 11/2$ ground state with the parameters $g = 2.03$ and $D = -0.46$ cm$^{-1}$. Single-crystal magnetic studies show hysteresis of molecular origin at $T < 1.2$ K with fast quantum mechanical tunnelling at zero field.

The reaction of cobalt(II) with citrate ions [L₆₈]$^{4-}$ yields a hexameric complex with the formula $\{[Co₄(L₆₈)]_₂[Co(H₂O)]_₂\}^{4-}$ (Fig. 17). Magnetic measurements show that this cluster behaves as a single-molecule magnet, displaying the largest energy barrier to reorientation of the magnetization for a non-manganese-based SMM. Increasing the crystallisation temperature of [Ni₈(L₆₈)₆(OH)₂(H₂O)₂]¹⁰⁻ causes a desolvation...
process that leads to structural rearrangement of the cluster to \([\text{Ni}_{8}(\text{L}^{68})_{6}(\text{OH})_{2}]^{10-}\) with distinct magnetic properties.\(^{42}\)

A range of nickel(II)-based clusters has been characterized including tetranuclear nickel(II) complexes with \(\mu_3-1,1,3\)- and \(\mu_4-1,1,3,3\)-azide bridges,\(^{43}\) a range of oximate-bridged tetranuclear nickel(II) rhombs,\(^{44}\) and some hydroxyquinaldine-bridged cobalt and nickel cubanes.\(^{45}\) Furthermore, some novel cluster topologies for nickel(II) have also been found with the incorporation of alkaline-earth metals in the formation of \([\text{Ni}_{8}^{II}\text{Mg}^{II}]_{2}\) and \([\text{Ni}_{8}^{II}M^{II}]_{2}\) (\(M = \text{Sr, Ba}\)) cages\(^{46}\) and novel trinculear dipyridylamido complexes of the first-row transition metals, \(\text{M}_3(\text{dpa})_4\text{Cl}_2\) [dpa\(^-\) is the anion of \(\text{di}(2\text{-pyridyl})\text{amine} = \text{L}^{69}\); \(M = \text{Cr, Co, Ni, Cu}\)], have been reported. These compounds are interesting as they allow examination of possible induction metal–metal bonded interactions when the complexes are reduced.\(^{47}\)

An extended tritopic picolinic dihydrazide ligand with terminal oxime groups (\(\text{H}_4\text{L}^{70}\)) undergoes spontaneous self-assembly in the presence of copper acetate to produce a unique \(\{\text{Cu}_{36}\}\) cluster of the form \([\text{Cu}_{36}(\text{L}^{70})_{12}(\mu_3-\text{OH})_8]^{16+}\) (Fig. 18) which

![Fig. 18 Representation of the structure of \([\text{Cu}_{36}(\text{L}^{70})_{12}(\mu_3-\text{OH})_8]^{16+}\).](image)
exhibits magnetic properties that utilise intramolecular antiferromagnetic exchange pathways.48

A range of lower-nuclearity copper(II) complexes has also been identified. For instance, a hexa-copper(II) ‘barrel cluster’ with a spin ground state $S = 3$ has been constructed with eight chelating L-prolinato-type ligands, which in turn provide the eight oxygen donors trapping a sodium ion in the centre. The structure of the $[\text{Cu}_6\text{Na}]$ unit in the discrete system and in the infinite cluster-chain are essentially the same and both display intra-unit ferromagnetic super-exchange.49 In a further study, trimethyltriazacyclohexane was used as a bridging ligand for triangular units, and C–H hydride abstraction was observed to occur in a Cu$_6$ cluster when complexation of $[\text{Cu}(\text{MeCN})_4](\text{BF}_4)$ with $N,N',N''$-trimethyl-1,3,5-triazacyclohexane in CH$_2$Cl$_2$ was performed. As such this leads to two clusters containing the triazacyclohexane as a ligand to triangular units with the abstraction and incorporation of chloride and hydride.52 In a copper(II)-based triangle, symmetry lowering and electron localization of a doublet spin state was observed, this being the one of the simplest forms of a spin-frustrated equilateral triangular lattice.53 Many types of tetraneuclear clusters have been isolated with many new types being discovered.54–58

Further, the formation of an interesting heterometallic cluster was reported when the encapsulation of paramagnetic vanadium(IV) in an antiferromagnetically-coupled dodecanuclear copper(II) cage was accomplished. A $\{\text{Cu}_{12}\}$ cluster is formed around a $\{\text{VO}_5\}$ giving the overall formula $[\text{Cu}^{\text{II}}_{12}\text{VIVO}_5\text{L}_{71}]$ $\{\text{H}_3\text{L}_{71}\}$ is $N,N'$-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine)} (Fig. 19).59

The first example an oxo-bridged $\{\text{Zn}_6\}$ octahedron with a central zinc(II) cation has been isolated from the hydrothermal reaction of $N$-(phosphonomethyl)-$N$-methylglycine, MeN(CH$_2$CO$_2$H)(CH$_2$PO$_3$H$_2$) (H$_3$L$_{72}$), with zinc(II) acetate. The cluster has the formula $\{\text{Zn}_6\text{L}_{72}\}$ in which seven zinc(II) cations form an unusual Zn$_6$(Zn)-centred octahedron with six of its Zn$_3$ triangular faces each further capped by a phosphonate group.60 Several interesting silver(I)-based clusters have also been synthesized including supramolecular triangular and linear arrays of metal–radical solids using pyrazolato-silver(i) motifs,61 and highly luminescent trimetallic Ag(I) complexes.62

The pace of development in manganese cluster chemistry has accelerated during the past months, one of the highlights of which was the isolation of the $\{\text{Mn}_{84}\}$ wheel (see Section 3).26 A large $\{\text{Mn}_{30}\}$ cluster has also been synthesized by the same group which also utilises the archetypal $\{\text{Mn}_{12}\}$ SMM as a precursor to yield $[\text{Mn}_{30}\text{O}_{24}(\text{OH})_8(\text{O}_2\text{CCH}_2\text{Bu})_{32}(\text{H}_2\text{O})_2(\text{MeNO}_2)_4]$ (in which the oxidation states can be assigned as follows: $3\text{Mn}^{\text{II}}, 26\text{Mn}^{\text{III}}, \text{Mn}^{\text{IV}}$). The structure of a central backbone is a
near-linear $[\text{Mn}_4\text{O}_6]$ unit, to either side of which are attached two $[\text{Mn}_{13}\text{O}_9(\text{OH})_4]$ units (Fig. 20). Magnetic investigations demonstrate that the cluster is a SMM but no clear steps characteristic of quantum tunnelling of magnetization are observed.

The reaction of the neutral triangle $[\text{Mn}_3\text{O}(\text{PhCOO})_6(\text{py})_2(\text{H}_2\text{O})]$ with 1,1,1-tris(hydroxymethyl)ethane ($\text{H}_3\text{L}^67$) affords novel dodecanuclear and octanuclear manganese complexes with unusual ladder-like cores built from edge-sharing
triangles and with SMM-like behaviour (Fig. 21). High-nuclearity cages can also be constructed via the dimerisation of a manganese triangle under solvothermal conditions.65

A large variety of other Mn complexes have been found including hexanuclear manganese(II) single-molecule magnets based on the reaction of Mn(O2CMe)2 with salicylaldoxime which yields [Mn6O2(O2CMe)2(L73)6EtOH4] (HL73 is salicylaldoxime).66 Also, a trigonal-bipyramidal cyanide cluster with SMM properties67 and a \{Mn8\}-based mixed-valence (MnIV6MnIII2) compound have been reported,68 as well as novel octa- and tetra-nuclear clusters formed in reactions with di-2-pyridyl ketone and phenyl 2-pyridyl ketone oxime.69 Reaction of manganese salts with di-pyridyl ketone oxime yields a cationic 24-MC-8 manganese cluster of the form \[\text{[MnII}_4\text{MnIII}_6\text{MnIV}_2(m_4-O)_2(m_3-O)_4(m_3-OH)_4-(m_3-OCH}_3)_2\text{L74}]\text{(OH)}(\text{ClO}_4)_3\] (L74 ~ di-pyridyl ketone oxime).70 The classical \{Mn12\} unit has even been derivatised with mixed carboxylate–sulfonate ligation: \[\text{[Mn}_{12}\text{O}_{12}(\text{O}_2\text{CMe})_{8}(\text{O}_3\text{SPh})_{8}(\text{H}_2\text{O})_{4}]\].71

Furthermore, a heterometallic hexanuclear cluster \{Mn4Ni2\} with an S ~ 8 spin ground state has been synthesised.72 and polynuclear manganese complexes with the dicarboxylate ligand m-phenylenedipropionate have been used to generate a number of other clusters with different nuclearities and oxidation states.73 Routes to high-nuclearity, fluoride-based octametallic and tridecametallic clusters of manganese have also been accessed,74 as well as a range of other Mn-based clusters.63,75–77

5 Polyoxometalates

The non-cyclic polyoxo(thio)molybdate(v)-sulfite \[\left[\text{Mo}_2\text{O}_6\text{(μ-S)}_2\text{O}_2\right]\text{[μ}_3\text{-SO}_3\right]_4(μ-\text{SO}_3)_{12}]^{20–}\] was prepared by self-condensation of the \[\text{[Mo}_2\text{O}_6\text{(μ-S)}_2\text{O}_2]\text{2+}\] building block. The overall cluster contains 12 Mo\textsuperscript{v} centres within the main structural unit. Each molybdenum atom has octahedral coordination and is bonded to a terminal oxo group, two μ-S2 ions and three sulfite (two μ- and one μ3-) oxygen atoms. The 12 Mo\textsuperscript{v} atoms form six binuclear units \[\text{[Mo}_2\text{O}_6\text{(μ-S)}_2\text{O}_2]\text{2+}\] with a Mo\textsuperscript{v}–Mo\textsuperscript{v} separation of

![Fig. 21](image-url) Structure of the \{M12\} (LHS) and the \{Mn8\} (RHS).
2.828(7) Å (indicative of a single bond). Furthermore, the six \([\text{Mo}_2^2\text{(μ-S)}_2\text{O}_2]_6\text{O}_3\) moieties are connected to each other by 16 sulfite ligands. This compound demonstrates the versatility of the sulfite anion in the formation of polyoxometalate clusters \(^{78}\) (Fig. 22).

A new family of Dawson-based \(\{\text{Mo}_{18}\}\) polyoxometalate clusters has been discovered that incorporates two pyramidal \(C_{3v}\) anions rather than the normal \(T_d\) anions of the form \([\text{Mo}_{18}\text{O}_{54}\text{SO}_3]^4^-\). In this case the \(\text{SO}_3^{2-}\) anions exhibit interesting supramolecular \(S\cdots S\) interactions and the new clusters demonstrate thermochromic behaviour between 77 and 500 K \(^{79}\) (Fig. 23).

A tetranuclear, manganous, Wells–Dawson sandwich-type polyoxometalate has been synthesized by the reaction of \(\kappa\text{-Na}_{12}(\text{As}_2\text{W}_{15}\text{O}_{56})\) with an aqueous solution of

---

**Fig. 22** Structure of \([\text{Mo}_2^2\text{(μ-S)}_2\text{O}_2]_6\text{O}_3\text{S}_2\text{(μ-SO}_3\text{)}_4\text{(μ-SO}_3\text{)}_{12}]^{20^-}\); the sulfur atoms are shown in grey.

**Fig. 23** Structure of \([\text{Mo}_{18}\text{O}_{54}\text{SO}_3]^4^-\); the sulfur atoms are shown in grey.
MnCl₂, and has the structure \( \alpha \beta \gamma \alpha \beta \gamma \alpha_{16}(\text{Mn}^{II} \text{OH}_2)_2 \text{Mn}^{II}_2(\text{As}_2 \text{W}_{15} \text{O}_{56})_2 \) (1). Electrochemical studies reveal that the presence of arsenic shifts the Mn waves to more positive potentials. Catalytic studies confirm that 1 is a significantly better catalyst for the \( \text{H}_2\text{O}_2 \)-based epoxidation of cis-cyclooctene, cyclohexene, and 1-hexene than its counterpart containing P in place of As.⁸⁰

A new synthetic approach to the synthesis of new low-nuclearity polyoxometalate (POM) clusters has been achieved using ‘shrink wrapping’ counter ions in the synthesis of anionic POM clusters. This approach appears to allow the formation of cluster frameworks with unsymmetrical topology, low symmetry, and high negative charge such as \( \text{H}_2\text{M}_{16}\text{O}_{52}^{10-} \). The formation of symmetrical aggregates appears to be restrained and the \( \text{H}_2\text{M}_{16}\text{O}_{52}^{10-} \) cluster demonstrates a high nucleophilicity and can bind two divalent transition metal ions (Fe\(^{II}\), Mn\(^{II}\), Co\(^{II}\), Ni\(^{II}\), or Zn\(^{II}\)) to its framework yielding a family of isostructural complexes, \( \text{Fe}_2(\text{H}_2\text{O})_8\text{H}_2\text{M}_{16}\text{O}_{52}^{6-} \) (Fig. 24).

A derivatised, Anderson-type POM cluster has been synthesized using a solvothermal reaction to yield a cationic heteropolyoxovanadium(IV) cluster, \( \text{Mn}^{IV}_6\text{O}_6\{(\text{OCH}_2\text{CH}_2)_2\text{N}(\text{CH}_2\text{CH}_2\text{OH})\}_6 \rangle^{2+} \), containing a fully reduced new cyclic \( \{\text{MnV}_6\text{N}_6\text{O}_{18}\} \) core with the Anderson structure. Interestingly, one pendant arm of each one of the six triethanolamine ligands (L\(^{75}\)) projects outward from the

![Fig. 24 Depiction of the structures of \( \text{H}_2\text{M}_{16}\text{O}_{52}^{10-} \) (top) and \( \text{Fe}_2(\text{H}_2\text{O})_8\text{H}_2\text{M}_{16}\text{O}_{52}^{6-} \) (bottom); the Fe ions are shown as light grey spheres.](image-url)
hexagonal ring and is involved in hydrogen bonding with two spectator, charge-balancing chloride ions. A supramolecular tetradecanuclear copper(II) polyoxotungstate has been discovered that is comprised of four trivalent tungsten-based POM Keggin clusters of the form \[ \left\{ [(\text{SiW}_{9}\text{O}_{34})(\text{SiW}_{9}\text{O}_{33}(\text{OH}))(\text{Cu(OH)})_{6}\text{Cu}]_{2}X \right\}^{23-} \], where X is Cl or Br and acts a central template bridging six copper(II) ions. The inclusion of a large number of first row transition metal ions in these clusters is interesting and may provide a basis for further development. A hydrothermally synthesized new octameric ring, \([\text{Mo}_8\text{S}_4\text{O}_{12}(\text{OH})_8(\text{C}_2\text{O}_4)]^{2-}\), has been synthesized and characterized whereby the ring-shaped anion is built up by novel \([\text{Mo}_2\text{SO}_3]\) building blocks via edge-sharing connections (Fig. 25).

A terpyridine ligand is covalently linked to a hexamolybdate cluster through the Mo–N imido bond to yield an interesting hybrid POM–ligand complex (Fig. 26). The derivatised ligand \((\text{H}_2\text{L}^{76})\)

![Structure of \([\text{Mo}_8\text{S}_4\text{O}_{12}(\text{OH})_8(\text{C}_2\text{O}_4)]^{2-}\); the sulfur atoms are shown as large grey spheres.](image.png)

is connected to the cluster via a Mo–N triple bond. This result opens the way for the preparation of hybrids containing covalently bonded transition metal complexes and polyoxometalate clusters.

Indeed, the formation of hybrid POM-based materials continues to be explored with the formation of networks based on \([\text{Mo}_6\text{O}_{19}]^{2-}\) POMs and crown ethers.
tungsten-based Keggins and copper(II)(bipy) complexes. There are also some interesting POM-based spiral architectures based on the linkage of Anderson-based POMs with Cu(II)bipy units as well as a one-dimensional infinite double helicate formed by the bridging of Mo(VI) and Gd(III) ions by l-tartrate to yield an enantiopure, left-handed double helical chain.

There have been a number of advances in the synthesis of ultra-large polyoxometalate clusters including the isolation of a new type of inclusion species \([\text{Mo}^{VI}_{114}\text{Mo}^{V}_{32}\text{O}_{429}(\text{H}_2\text{O})_{50}(\text{KSO}_4)_{16}]^{30-}\). This comprises 16 encapsulated K\(^+\) and SO\(_4^{2-}\) ions and shows an unusual 64-membered \{K(SO\(_4\))\}_{16} ring embedded into a wheel-shaped-type cluster host (Fig. 27). This is interesting as it means that the archetypal mixed-valence Mo wheels can be derivatised in extremely subtle ways to produce complex inclusion compounds.

Further developments in ultra-large spherical POM clusters with the composition \((\text{pent})_{12}\text{(linker)}_{30} \cong \{(\text{Mo})\text{Mo}_5\text{O}_{21}(\text{H}_2\text{O})_{6}\}_{12}\{\text{Mo}_2\text{O}_4\text{(ligand)}\}_{30}\) have been possible by manipulating the linker groups. When the linker is SO\(_3^{2-}\) or HPO\(_4^{2-}\) the cluster is able to take up cations so the uptake leads to stoichiometric preferences, i.e. \{Mo\(_9\)O\(_9\)\} pores can function like a type of crown ether. Furthermore, these pores can act like primitive ion channels allowing the assembly of ions within and below the pore (Fig. 28). In addition, the \((\text{pent})_{12}\text{(linker)}_{30}\) clusters have been found to be interesting vessels in which to study the assembly of water and small cations.

6 Capsules, threaded molecules and porphyrin assemblies

A molecular capsule has been synthesized that traps pyridine molecules via a combination of hydrogen bonding and copper(II) coordination. The capsule comprises an octameric Cu(II) complex, \(\text{[Cu}_8\text{(L}^{77}\text{)}_8\text{(py)}_4\text{(H}_2\text{O})_8]\), synthesized from the tetradenate deprotonated ligand (L\(^{77}\)) (Fig. 29).
The platinum-based building block L\textsuperscript{78} complexes with copper(ii) to yield a complex that contains a metal-centre hydrophobic pocket that has been shown to recognise pyridine.\textsuperscript{94}

Ligand-directed molecular architectures have been assembled with cavities that can include anionic guests with the combination of L\textsuperscript{79}–\textsuperscript{81} with silver(i) salts (Scheme 1).

These cavities comprise two-dimensional rectangular metallacycles and three-dimensional trigonal or tetragonal prisms.\textsuperscript{95} Silver-based triangular cages have also been produced using more flexible ligands (L\textsuperscript{82}, L\textsuperscript{83}).\textsuperscript{96}

Bowl-shaped superstructures have been constructed by intra-clipping of resorcin-[4]arene derivatives (L\textsuperscript{84}) with two equivalents of (en)Pd(NO\textsubscript{3})\textsubscript{2} in water and this cavity encloses several nitrate anions (Fig. 30).\textsuperscript{97}

Fig. 27  Representation of the structure of [Mo\textsuperscript{VI}\textsubscript{114}Mo\textsuperscript{V}\textsubscript{32}O\textsubscript{429}(H\textsubscript{2}O)\textsubscript{50}(KSO\textsubscript{4})\textsubscript{16}]\textsuperscript{30--}.

Ligand-directed molecular architectures have been assembled with cavities that can include anionic guests with the combination of L\textsuperscript{79}–\textsuperscript{81} with silver(i) salts (Scheme 1).

These cavities comprise two-dimensional rectangular metallacycles and three-dimensional trigonal or tetragonal prisms.\textsuperscript{95} Silver-based triangular cages have also been produced using more flexible ligands (L\textsuperscript{82}, L\textsuperscript{83}).\textsuperscript{96}

Bowl-shaped superstructures have been constructed by intra-clipping of resorcin-[4]arene derivatives (L\textsuperscript{84}) with two equivalents of (en)Pd(NO\textsubscript{3})\textsubscript{2} in water and this cavity encloses several nitrate anions (Fig. 30).\textsuperscript{97}
Bowl-shapped cavitands have also been shown to self-assemble on surfaces to produce nano-structures. Calixarenes continue to be explored as novel cavity-defining ligands, increasingly with harder metal ions such as titanium and europium ions bound to phenolate moieties.

A simple general ligand system for assembling octahedral metal-rotaxane complexes has recently been described producing complexes of the form \((\text{ML}_{85}\text{L}_{86}(\text{py})_{8}(\text{H}_{2}\text{O})_{8})\). This is interesting as the imine-based ligand appears to assist in the efficient assembly of [2]rotaxanes around octahedral metal ions in a

Fig. 28  Representations of the structure of the \((\text{pent})_{12}(\text{linker})_{30}\) cluster. A stick representation is shown on the LHS and a polyhedral representation of the RHS. In both case the \(\{\text{Mo}_{9}\text{O}_{9}\}\) ‘pores’ are visible.

Fig. 29  Representation of the \([\text{Cu}_{8}(\text{L}_{77})_{8}(\text{py})_{8}(\text{H}_{2}\text{O})_{8}]\) hydrogen-bonded capsule.

Bowl-shapped cavitands have also been shown to self-assemble on surfaces to produce nano-structures. Calixarenes continue to be explored as novel cavity-defining ligands, increasingly with harder metal ions such as titanium and europium ions bound to phenolate moieties.

A simple general ligand system for assembling octahedral metal-rotaxane complexes has recently been described producing complexes of the form \((\text{ML}_{85}\text{L}_{86}(\text{ClO}_{4})_{2})\). This is interesting as the imine-based ligand appears to assist in the efficient assembly of [2]rotaxanes around octahedral metal ions in a
Scheme 1

353
five-component self-assembly reaction, producing rotaxanes under true thermodynamic control (Fig. 31).\textsuperscript{102}

A polymeric rotaxane has been constructed from the inclusion complex of \(\beta\)-cyclodextrin (L\textsuperscript{87}) and 4,4’-dipyridine (L\textsuperscript{88}) by coordination of nickel(II) ions.\textsuperscript{103} A [2]catenane has been constructed around a Ru(diimine)\textsubscript{3}\textsuperscript{2+} which has been utilised as

\textbf{Fig. 30} Representation of the structure of \([\text{Pd(en)}\textsubscript{2}]_2[L\textsuperscript{84}]\textsuperscript{4+}\) with two nitrates present in the cavity.
a template (Scheme 2). In this way a macrocycle with one bidentate chelate is formed once threaded through the macrocycle with two bidentate chelates, and cyclisation completes the formation of the complex, although other routes involving reactions at the periphery of coordinated units have also been developed.

The synthesis of the two-ring intermediate en route to a Borromean link in the orthogonal-ring has been reported. This is interesting as the threaded system containing L represents a precursor to the Borromean link (Fig. 32).

Fig. 31 Representation of the crystal structure of the [2]rotaxane [(ML\textsuperscript{85,86})\textsuperscript{2+}]; the tBu groups have been omitted for clarity.

Scheme 2 Depiction of the synthetic strategy to form a [2]catenane using a coordination template route.

Encapsulated transition metal catalysts have been formed via a simple self-assembly processes involving porphyrin and pyridylphosphine-based ligands (L$^{91}$, L$^{92}$). These form new types of encapsulated catalysts with increased turnover and selectivity for the rhodium-catalyzed hydroformylation of 1-octene.$^{107,108}$

A hexameric assembly of porphyrins has been designed as a light-harvesting antenna mimic, (L$^{93}$Zn$_2$)$_6$. The complex was shown to have a circular topology, constructed from interlocking $m$-gable-porphyrins by slipped-cofacial dimer formation without the need for a protein matrix. These may be important in the construction of
light-harvesting complexes; indeed, another study has shown that it is possible to observe efficient excitation energy transfer in long, *meso–meso*-linked Zn(II) porphyrin arrays.\textsuperscript{110}

A supramolecular assembly of linear tri-nickel complexes incorporating metallo-porphyrins has been assembled using L\textsuperscript{91} and L\textsuperscript{69},\textsuperscript{111} and a modified tetraphenyl porphyrin has been used to form a supramolecular capsule in which a \{Au\textsubscript{55}\} cluster has been encapsulated.\textsuperscript{112} Further, a range porphyrin monomer, dimer and oligomeric stacked Eu(III) complexes has been constructed and investigated electrochemically.\textsuperscript{113} In addition, a rhodium(III) porphyrin cyclic tetramer and cofacial dimer have been synthesized,\textsuperscript{114} as well as a porphyrin–cyclodextrin assembly with a molecular wedge.\textsuperscript{115}

7 Squares, triangles, boxes and grids

Increasingly, the concepts of ligand design and self-assembly are being exploited in a well-defined manner to create enormous and intricate molecules, in what can be understood as a type of cooperative process.\textsuperscript{116} The bowl-shaped triarylphosphane ligands L\textsuperscript{94} and L\textsuperscript{95} react with Pd(II) salts to give an interesting trinculear complex, [(PdX\textsubscript{2})\textsubscript{3}(L\textsuperscript{94–95})\textsubscript{2}], whose formation appears to be facilitated by the bowl shape of the ligands.\textsuperscript{117} Tri- and hexa-nuclear platinum complexes have been assembled that are rather dendrimer-like to give a \{Pt\textsubscript{18}\} cluster dendrimer.\textsuperscript{118}

Platinum(II) terpyridyl-capped, carbon-rich molecular rods with alkynic spacers have been synthesized wherein two Pt centres are linked by a (C=C–C=C) unit and...

capped with a terpyridyl-based ligand \( (L^{96} = \text{Bu}_3\text{-tpy} = 4,4',4''\text{-tri-}\text{tert}-\text{butyl}-2,2':6',2''\text{-terpyridine}) \). The complexes, of the type \([L^{96}\text{Pt–C=C–C=PtL}^{96}]^{2+}\) were found to have interesting luminescent properties (Fig. 33).

The use of a ligand with two non-equivalent binding sites, \( L^{97} \), leads to a hexanuclear cage complex \([M_6L^{97}X](X)_5\) \([M = \text{Cu}(i), \text{Ag}(i); L^{97} = 6,6'\text{-bis(4-ethynylpyridine)2,2'-bipyridine}; X = \text{BF}_4^−, \text{SbF}_6^−]\). This has been prepared using a self-assembly approach and encapsulates anions in the solid state and is fluxional in solution (Fig. 34).

Potential polynuclear platinum antitumor complexes have been designed using a polydentate ligand system based on dipyridylamine and 1,3,5-trimethylenebenzene to give the hexadentate ligand, \( N,N,N',N'',N''\text{-hexa(2-pyridyl)-1,3,5- tris(aminomethyl)benzene} (L^{98}) \) The trinuclear Pt(II) complex \([\text{Pt}_3L^{98}L^{99}] (L^{99} = \text{cyclobutane dicarboxylic acid})\) shows a high affinity for DNA.

---

Fig. 33  Structure of the rod-shaped \([L^{96}\text{Pt–C=C–C=PtL}^{96}]^{2+}\) complex.
Molecular receptors consisting of either two parallel, cofacially disposed, terpyridyl–Pd–Cl$^+$ or terpyridyl–Pt–Cl$^+$ units, [L$^{100}$(MCl)$_2$]$^{2+}$, and their interaction with a range of guests have been recently investigated. The association constants found for the neutral guest with the palladium and platinum receptors are large and it is suggested that metal–metal interactions contribute to the molecular recognition.

The new fluorinated rigid ligand 1,4-bis(4-pyridyl)tetrafluorobenzene (L$^{101}$) was used in combination with different diphosphine Pd(II) and Pt(II) triflates to build metallo-supramolecular assemblies. Complex equilibria between triangular and square entities were detected for all the cases and the square/triangle ratio was seen to depend upon several factors, such as the nature of the metal corners, the

Fig. 34 Depiction of the structure of [Ag$_6$L$^{97}$SbF$_6$]$^{5+}$. 

concentration, and the solvent,\textsuperscript{123} although ligand design can be used to synthesize ligands that exclusively form triangular architectures.\textsuperscript{124}

A supramolecular dimeric rhomboid and its trimeric counterpart, a hexagon, are generated by design \textit{via} the directional bonding methodology of self-assembly using $L^{102}$ as a building block.

The different-sized supramolecular macrocycles formed by Pt-coordination undergo a concentration- and temperature-dependent dynamic equilibrium.\textsuperscript{125} A range of other similar architectures is also accessible.\textsuperscript{126–128}

A novel tetra-ferrocenyl-substituted ligand, $L^{103}$, has been designed that can form molecular squares on complexation with Pt(II) salts.

Formation of the molecular square assembles 16 ferrocenyl groups in one molecular network (Scheme 3). Electrochemical investigations of these unprecedented multiredox-active dendritic molecular squares show that the redox behaviour of the ferrocene units is influenced by the square superstructure.\textsuperscript{129}

The reaction of $[\text{CpCo(CN)}_3]^-$ with $[\text{Cp}^*\text{Ru(MeCN)}]^+$ in the presence of EtNH$_3^+$ causes the formation of a molecular box (Scheme 4) with a large empty void of \textit{ca.}
Furthermore, this [Ru$_4$Co$_4$] box is able to bind various, large mono-valent cations ranging from Cs$^+$ to MeNH$_3^+$. Further studies showed that it was possible to produce ‘defect’ boxes (Fig. 35).

The stepwise assembly of a tetranuclear species that contains four identical cobaltacarborane clusters and features a planar octagonal (tetratruncated square) $\{C_{16}B_8\}$ macrocycle has been realised. This has a planar geometry and electrochemical studies reveal significant intramolecular electronic communication (Fig. 36).

A supramolecular cube, [(Cp*WS$_3$Cu$_3$)$_8$Cl$_8$(CN)$_{12}$Li$_4$], has been synthesized with linking cyanide anions that connect the Cp*WS$_3$Cu$_3$ clusters to form a cube. The ‘cube’ dimensions as judged by the separation of W centres are 9.64 $\times$ 10.10 $\times$ 10.10 Å (Fig. 37). Preliminary photochemical and photophysical investigations of the cube reveal very interesting photoluminescent properties in the solid state at ambient temperature (Fig. 37).

Reaction of the bis-bidentate ligand L$^{104}$, having two bidentate pyrazolyl–pyridine termini, with Co(II) or Zn(II) results in formation of the complexes [M$_8$(L$^{104}$)$_{12}$]X$_{16}$...
(X = perchlorate or tetrafluoroborate); \([\text{Zn}_8(\text{L}^{104})_{12}]\text{(ClO}_4)_{16}\) has been structurally characterized and is a cube with a metal ion at each corner, a bridging ligand along each edge, and an anion in the central cavity. Interestingly, the cube has \(S_6\) symmetry and is distorted (Fig. 38).\(^{133}\)

**Fig. 35** Representation of the structure of the defect box, \(\{\text{Cs}[\text{Cp}^*\text{Rh(CN)}_3][\text{Cp}^*\text{Ru}]_3\}\).

**Fig. 36** Depiction of the structure of the \(\{\text{C}_16\text{B}_8\}\), \([\text{Cp}^*\text{Co}(2,3-\text{Et}_2\text{C}_2\text{B}_4\text{H}_3-5-\text{C}==\text{C}-7-\text{C}==\text{C})]_4\).

The use of cis,cis-1,3,5-triaminocyclohexane (tach = L105) as a capping ligand in generating metal–cyanide cage clusters with accessible cavities is demonstrated via the reaction of [(tach)M(CN)3] (M1 = Fe, Co) and [M2(H2O)6]2+ (M2 = Ni, Co) to yield [(tach)4(H2O)12M14M24(CN)12]8+ [Fig. 39(left)]. The compound [(tach)Cr(CN)3]...
reacts with \([\text{Ni(H}_2\text{O)}_6]^{2+}\) in aqueous solution to produce \([\text{tach}]_8\text{Cr}_8\text{Ni}_6(\text{CN})_{24}]^{12+}\), featuring a structure based on a cube of \(\text{Cr}^{III}\) ions with each face centred by a square planar \([\text{Ni(CN)}_4]^{2-}\) unit [Fig. 39(right)]. In another study the other isomer of tach, \(\text{cis,trans-1,3,5-triaminocyclohexane (t-tach} = \text{L}^{106}\), has been used in the assembly of a variety of \(\text{Pd}(II)\)-based architectures from monomers, to trimeric and hexameric \(\text{Pd}(II)\) complexes.135

A new tetrakis[(2-pyrimidinylethynyl)cyclobutadiene][(cyclopentadienyl)cobalt] complex has been synthesized (CoCpL\(^{107}\)) which is extremely well preorganized to form molecular squares.

Complexation with \(\text{HgCl}_2\) yields \([(\text{CoCpL}^{107})\text{HgCl}_2]\) wherein the mercury is in an unusual square planar coordination environment, and two DCM molecules are bound into the square by hydrogen-bonded interactions (Fig. 40).136 It is worth noting a few other square-like complexes have also been synthesized containing \(\text{Ru}(II)^{137}\) and \(\text{Cu}(II)^{138}\).
A number of molecular ‘grids’ have been synthesized and characterized; for example, the new bis-hydrazone-based ligand L^{108} forms ionisable [2 × 2] grid-type transition metal complexes whose properties may be modulated by multiple protonation/deprotonation as shown by the reversible change in optical properties of the [Co^{II}_4 L^{108}_4]^{8+} complexes depending on their protonation state (Fig. 41).^{139}
A similar [2 × 2] grid is formed via the reaction of L^{109} with Cu(II) salts^{140} whereas L^{110} forms a [4 × (2 × 2)]-{Pb_{16}} grid structure, with an overall size of ca. 2.6 nm^{141} (Fig. 42) and similarly large ‘nano-grids’ have been reported by others also.^{142}

8 Helicates and extended helical frameworks

The self-assembly between a bis-monodentate tecton based on two pyridine units, L^{111}, connected to an enantiomerically pure isomannide stereoisomer and HgCl_{2} leads to the formation of an enantiomerically pure triple-stranded, helical, infinite coordination network.^{143}

The tecton approach has also been used for double-stranded helicates.^{144} Furthermore, a novel, extended, covalent tripod, L^{112}, designed for assembling triple-helical, nine-coordinated lanthanide(III) podates has been synthesized. Reaction with lanthanide(III) in acetonitrile produces stable and dynamically inert

$C_3$-symmetrical podates $[\text{Ln}(L^{112})]^3^+$ ($\text{Ln} = \text{La–Lu}$) in which $\text{Ln}^{III}$ is nine-coordinate in a pseudo-tri-capped trigonal prismatic site.\(^{145}\)

In addition, a helical complex based on the salen ligand has also been obtained.\(^{146}\)

The synthesis, structural characterization, and magnetic properties of the first triple-stranded helicate containing four metal centres $[\text{Cu}_4(L^{113})_3](\text{ClO}_4)_8$ that exhibits intramolecular magnetic exchange between metal centres has been formed through the self-assembly of $L^{113}$ and Cu(ClO$_4$)$_2$ (Fig. 43).\(^ {147}\)

A chiral tetraketone ligand, $L^{114}$, was obtained by Claisen-type condensation of 4-bromoacetophenone with the acetone ketal of $L$-tartric acid diethyl ester and leads, with gallium(III) or iron(III) ions in self-assembly processes, to dinuclear helicate-type cryptands which are able to bind lithium cations.\(^ {148}\)

A hexanuclear copper(II) complex with a figure-of-eight strip topology is formed by metal-directed self-assembly of tritopic ligand $L^{115}$, bis-bidentate glycine hydroxamic acid and Cu(II) ions in a $2:2:6$ ratio (Fig. 44).\(^ {149}\)

The synthesis and structural characterization of a novel $C_3$-symmetric tris-bidentate ligand, $L^{116}$, featuring a triphenylamine core appended by pyridylimine coordination has been achieved.\(^ {150}\)$^1$H NMR compleximetric titration studies with Ag(I) and ESMS indicate the presence of $[\text{Ag}_3(L^{116})_2]^3^+$ species in solution, consistent with the formation of a trinuclear double-helicate complex. A new molecular ligand cage incorporating three bipyridyl units ($L^{117}$) has been synthesized by a conventional multi-step procedure using a Ni(II)-based templating procedure. Structural analysis
demonstrates that the central metal ion acts to promote a triple helical twist that extends ca. 22 Å along the axial length of the molecule (Fig. 45). 151

Copper(I) coordination has been investigated for three analogous pyridine–azine ligands, in which two pyridylimine binding units are linked directly through the imine nitrogen atoms. It has been found that substituents on the imine units of the ligands influence the metallo-supramolecular architecture adopted, leading to a dinuclear double-helicate L 118, a trinuclear circular-helicate, L 119, and a polymeric array, L 120. In each structure the copper(I) centre is four-coordinate, 152 and the effects of phenyl substituents introduced at the imine carbon (L 120) have been investigated. 153

Fig. 42  Representation of the [4 × (2 × 2)]–{Pb16} grid structure.

Fig. 43  Structure of the triple helicate based on L 113.

*Copper(I)* coordination has been investigated for three analogous pyridine–azine ligands, in which two pyridylimine binding units are linked directly through the imine nitrogen atoms. It has been found that substituents on the imine units of the ligands influence the metallo-supramolecular architecture adopted, leading to a dinuclear double-helicate L 118, a trinuclear circular-helicate, L 119, and a polymeric array, L 120. In each structure the copper(I) centre is four-coordinate, 152 and the effects of phenyl substituents introduced at the imine carbon (L 120) have been investigated. 153

371
A novel tubular coordination network [Zn(spcp)(OH)] (spcp = 4-sulfanyl methyl-4A-phenylcarboxylate pyridine = L\textsuperscript{121}) with a modest SHG activity and based on two types of homo-chiral helices was synthesized and characterized.\textsuperscript{154} Double-stranded [4 × 4] helicates, of Fe(II) and Mn(II), supported by an extended dipyrrolide ligand have also been synthesized. Transamination reactions between Mn and Fe

**Fig. 44** Structure of the figure-of-eight complex (top view LHS, side view RHS).
amides and the diiminodipyrromethane ligand, $H_2L^{122}$, result in the spontaneous formation of volatile, double-stranded helicates.\textsuperscript{155} Non-covalently bound ligand strands form interesting transition metal helicates that are linked via hydrogen-bonded interactions.\textsuperscript{156}

A layered zinc phosphate ($C_5H_6N_2$)\textsubscript{Zn}(HPO\textsubscript{3}) containing helical chains has been prepared hydrothermally from aminopyridine (L\textsuperscript{123}), H\textsubscript{3}PO\textsubscript{4} and Zn(II) acetate. The structure consists of left-handed and right-handed helical chains that are connected through oxygen atoms to form an undulated sheet structure with a 4.8-net.\textsuperscript{157} Hydrothermal synthesis has also been used to construct a pure molybdenum-oxide helical chain based on $[L^{124}]_2[\text{Mo}_9\text{O}_{30}]$ \cite{L124} $\text{NH}_3(\text{CH}_2)\text{NH}_2(\text{CH}_2)\text{NH}_3$.\textsuperscript{158} The chains comprise two novel and symmetrically-related helices which coexist in the centrosymmetric solid, in which the two kinds of helices appear in the left-handed and right-handed enantiomorphs, respectively (Fig. 46).

Columnar supramolecular architectures were self-assembled from $S_4$-symmetric coordination nanotubes encapsulating neutral guest molecules whereby a neutral coordination nanotube was assembled from four HgCl\textsubscript{2} units and four ditopic L\textsuperscript{125} ligands in a highly concerted fashion.

![Fig. 45](image)

**Fig. 45** Structure of the [Ni(L\textsuperscript{117})\textsuperscript{2+}] helical complex.

Two directional binding sites on the Hg(II) ion direct the assembly which is facilitated by the anti-conformation adopted by the ligand. Interestingly, the tubes are aligned such that they resemble a pipeline and these pipelines are arranged into a three-dimensional columnar architecture (Fig. 47).\textsuperscript{159}

Co(II) sulfate reacts with the flexible ligand 1,4-bis(imidazol-1-ylmethyl)benzene (L\textsuperscript{126}) to yield the coordination network $[\text{Co}(L^{126})_2(H_2O)_2](\text{SO}_4)$, containing polymeric ribbons of rings which penetrate and catenate a 3D single frame of the
CdSO₄ topology, to produce an open-channel entangled architecture with nanoporous behaviour. A new type of three-dimensional framework based on dodecanuclear Cd(II) macrocycles \([\text{Cd}_2\text{L}^{127}\text{L}^{128}\text{L}^{129}]_6\) \(\text{H}_2\text{L}^{127} = \text{diphenic acid; } \text{L}^{128} = \text{isonicotinic acid; } \text{L}^{129} = 1,2-\text{di}(4-\text{pyridyl})\text{ethylene}\) was prepared by the hydrothermal reaction and \textit{in situ} synthesis. The dodecanuclear Cd(II) macrocycles are cross-linked by \textit{exo}-tridentate isonicotinate ligands in their perpendicular direction to form a one-dimensional pillared framework. In this way the isonicotinate ligands serve as pillars linking the adjacent macrocycles along the \(z\)-axis through carboxylate oxygen atoms bridging between Cd(II) centres of the four-membered \(\text{Cd}_2\text{O}_2\) ring in one macrocycle and the pyridyl nitrogen atom binding to the non-semi-chelating Cd(II) in the other macrocycle.

A family of supramolecular inclusion solids based upon second-sphere interactions have been synthesized from \([\text{Co(NH}_3)_6\text{Cl}]_3\) and disulfonate anions. These form pillared layered structures and include guest molecules, \([[[\text{Co(NH}_3)_6\text{Cl}](\text{L}^{130})_6(\text{H}_2\text{O})_6]]_\infty\) \(\text{L}^{130} = 1,4-\text{piperazinebis(ethanesulfonate)}}\) and \([[[\text{Co(NH}_3)_6\text{Cl}](\text{L}^{131})_{1.5}(\text{H}_2\text{O})_2(\text{dioxane})]]_\infty\) \(\text{L}^{131} = 2,6-\text{naphthalenedisulfonate}\). The networks are sustained

by charge-assisted hydrogen bonding and show two different assembly motifs, one based on the complementarity of the edges of the triangular triamine faces with sulfonate groups, and the other on hydrogen-bond complementarity with the centroids of the triangular faces.\textsuperscript{162}

9 Supramolecular and macrocyclic devices

A complex capable of selective detection of zinc ions with a novel luminescent lanthanide probe has been designed. Out of the Tb\textsuperscript{III} and Eu\textsuperscript{III} diethylenetriamine-pentaacetic acid (DTPA)–bisamide complexes, [TbL\textsubscript{132}] gives Zn(II)-sensitive luminescence. The luminescence emission data also revealed very high selectivity for Zn\textsuperscript{II} ions compared with Ca\textsuperscript{II} and Mg\textsuperscript{II} ions. Notably, the luminescence emission enhancement in 100 \( \mu \)m HEPES buffer (pH 7.4) containing 5 mM Ca\textsuperscript{II} or Mg\textsuperscript{II} ions showed that these ions had no effect in the presence or absence of Zn\textsuperscript{II} ions.\textsuperscript{163}

An acoustic wave sensor for barium based on poly[Ni(L\textsubscript{133})] recognition chemistry has been developed whereby interfacial recognition of barium by a crown ether receptor is quantified using an acoustic wave sensor, and the isotherm characteristics rationalized in terms of solution complexation chemistry and polymer materials properties. The concept of encapsulating a solution-based complex within a polymer immobilized on an acoustic wave sensor has been implemented quantitatively.\textsuperscript{164}

\begin{itemize}
  \item An acoustic wave sensor for barium based on poly[Ni(L\textsubscript{133})] recognition chemistry has been developed whereby interfacial recognition of barium by a crown ether receptor is quantified using an acoustic wave sensor, and the isotherm characteristics rationalized in terms of solution complexation chemistry and polymer materials properties. The concept of encapsulating a solution-based complex within a polymer immobilized on an acoustic wave sensor has been implemented quantitatively.\textsuperscript{164}
\end{itemize}
Fluorophore-capped cyclodextrins have been shown to be efficient chemical-to-light energy converters. This is because the bisbenzimidazole-capped cyclodextrins, capable of forming supramolecules, harvest chemical energy from the oxidation reaction of a bis(aryl)oxalate and emit light two orders of magnitude more efficiently than fluorescein.\textsuperscript{165}

In an interesting study, the supramolecular assembly of a ferrocene–porphyrin conjugate allows ferrocene-based electrochemical sensing of the metalloporphyrin axial coordination via a ‘tail on–tail off’ binding process. This was demonstrated by electrochemical methods which showed that a self-assembly phenomenon, coupled with efficient electronic communication throughout the receptor, allows an unprecedented ferrocene-based electrochemical sensing of neutral species via a metalloporphyrin-centred ‘tail on–tail off’ binding process.\textsuperscript{166}

The Tb\textsuperscript{3+} complexes of cyclen-based aromatic diaza-15-crown-5 and 18-crown-6 ether conjugates were designed as luminescent switches for sodium and potassium where the delayed Tb(III) emission, occurring as line-like emission bands between 490 and 622 nm, was ‘switched on’ upon recognition of these ions in pH 7.4 buffered water solution.\textsuperscript{167}

A new biotinylated tris-bipyridinyl iron(II) complex was designed as a supramolecular biosensing architecture. The bioaffine immobilization of several avidin layers on an electrode modified by a biotinylated polymer was accomplished by the first biotinylated redox bridge consisted of a tris(bipyridyl) iron(II) complex bearing six pre-oriented biotin groups. It is interesting that the biotin-labelled iron(II) complex constitutes an efficient small building block for the reproducible immobilization of several avidin layers by affinity interactions.\textsuperscript{168}
Two new copper(Ⅰ) pseudorotaxanes bearing a thioctic acid appended unit have been prepared and deposited onto a gold electrode surface, leading to surface-attached electroactive pseudorotaxanes. These threaded molecules were attached onto a gold surface through the disulfide bridge and the electrochemical response in the solid state has been studied by electrochemical methods.169

$C_3v$ symmetric receptors were designed that show high selectivity and high affinity for phosphate ions. This was accomplished by creating cavities that are complementary to three faces of a tetrahedron.170

An interesting, water-based, azophenol-based chromogenic complex has been developed and examined that is able to detect pyrophosphate.171

A dinuclear metal ion complex $\text{Zn}_2(L^{134})$ was synthesized and studied as a catalyst for the cleavage of the phosphate diester 2-hydroxypropyl-4-nitrophenyl phosphate (HPNP). This complex was shown, via a variety of studies, to be an interesting model catalyst.172

Layer-by-layer growth of metal–metal-bonded supramolecular thin films was used in the fabrication of lateral nanoscale devices and these were directed by different substrate surfaces using monolayer templates. The thin films were studied using electrochemical techniques and the application of these multilayers as active materials for switching and other molecular devices is suggested.173

Molecular recognition and conductance in crown ethers have been studied as model quantum conductors using theoretical techniques. It was found that cationic binding should significantly lower conductance due to quantum mechanical interference effects, and there is no correlation between conductance and ligand type. This study opens the way for experimental measurements to examine these ideas.174

A ligand has been designed (L\textsuperscript{137}) that forms hairpin-shaped heterometallic luminescent lanthanide complexes for DNA intercalative recognition whereby the Ln–Pt\textsubscript{2} metallohairpins bear intercalating groups that direct the complex to DNA recognition. This leads to considerable DNA stiffening, and the lanthanide luminescent unit is ‘remote’ from the negatively-charged DNA backbone.\textsuperscript{175}

Building blocks for the molecular expression of quantum cellular automata have been designed and examined. These complexes met the basic requirements for a molecular QCA cell and as such contain dots consisting of metal complexes possessing two stable redox states and a planar array of four such complexes with 4-fold symmetry. This \{\(\eta^5\text{-}C_5\text{H}_5\)Fe(\(\eta^5\text{-}C_5\text{H}_4\))\}_4(\(\eta^4\text{-}C_4\)Co(\(\eta^5\text{-}C_5\text{H}_5\)))\textsuperscript{2+} complex possesses sufficient through-bond or through-space interaction that the 2-electron, 2-hole mixed-valence state is stable with respect to comproportionation to lower and higher oxidation states. It shows type II or type III mixed-valence behaviour appropriate for switching (Fig. 48).\textsuperscript{176}

A terbium-sensitized ytterbium luminescence has been reported from a trimetallic lanthanide complex containing two terbium ions and one ytterbium ion. The complex is the first report of lanthanide-centred near-IR emission sensitized by a lanthanide ion.\textsuperscript{177}

A bright phosphorescent trinuclear copper(\textit{i}) complex demonstrating interesting solvatochromism and ‘concentration luminochromism’ was recently reported. The trinuclear copper(\textit{i}) complex \{[3,5-(CF\textsubscript{3})\textsubscript{2}pz]Cu\}_3 \{where [3,5-(CF\textsubscript{3})\textsubscript{2}pz] = L\textsuperscript{138}\} exhibits multicolour, bright phosphorescent emissions that are sensitive to temperature, solvent, and concentration.\textsuperscript{178}

A functioning molecular machine, namely a supramolecular ‘nanovalve’ that opens and closes the orifices around ‘nanopores’ which accept and release small numbers of molecules on demand has been created. The nanopores are created using a one-step, one-pot, dip-coating technique, and they can be filled with guest molecules and
trapped by redox-controlled, gate-keeping supermolecules. An external reducing reagent can be used to break up the supermolecules, allowing the release of the guest molecules.\textsuperscript{179}
